Enhanced
Memory Systems Inc.

DM2202/2212 EDRAM 1Mb x 4 Enhanced Dynamic RAM

Product Specification

Features

- 2Kbit SRAM Cache Memory for 12ns Random Reads Within a Page
- Fast 4Mbit DRAM Array for 30ns Access to Any New Page
- Write Posting Register for 12ns Random Writes and Burst Writes Within a Page (Hit or Miss)
- 256-byte Wide DRAM to SRAM Bus for 14.2 Gigabytes/Sec Cache Fill
- On-chip Cache Hit/Miss Comparators Maintain Cache Coherency on Writes
- Hidden Precharge and Refresh Cycles
- Write-per-bit Option (DM2212) for Parity and Video Applications
- Extended 64ms Refresh Period for Low Standby Power
- 300 Mil Plastic SOJ and TSOP-II Package Options
- +5 and +3.3 Volt Power Supply Voltage Options
- Low Power, Self Refresh Mode Option
- Industrial Temperature Range Option

Description

The 4Mb Enhanced DRAM (EDRAM) combines raw speed with innovative architecture to offer the optimum cost-performance solution for high performance local or system main memory. In most high speed applications, no-wait-state performance can be achieved without secondary SRAM cache and without interleaving main memory banks at system clock speeds through 50MHz. Two-way interleave will allow no-wait-state operation at clock speeds greater than 100MHz without the need of secondary SRAM cache. The EDRAM outperforms conventional SRAM cache plus DRAM memory systems by minimizing processor wait states for all possible bus events, not just cache hits. The combination of data and address latching, 2K of fast on-chip SRAM cache, and simplified on-chip cache control allows system level flexibility, performance, and overall memory cost reduction not available with any other high density memory component. Architectural similarity with JEDEC DRAMs allows a single memory controller design to support either slow JEDEC DRAMs or high speed EDRAMs. A system designed in this manner can provide a simple upgrade path to higher system performance.

Architecture

The EDRAM architecture has a simple integrated SRAM cache which allows it to operate much like a page mode or static column DRAM.

The EDRAM's SRAM cache is integrated into the DRAM array as tightly coupled row registers. Memory reads always occur from the cache row register. When the internal comparator detects a page hit, only the SRAM is accessed and data is available in 12ns from column address. When a page read miss is detected, the new DRAM row is loaded into the cache and data is available at the output all within 30ns from row enable. Subsequent reads within the page (burst reads or random reads) can continue at 12ns cycle time. Since reads occur from the SRAM cache, the DRAM precharge can occur simultaneously without degrading performance. The on-chip refresh counter with independent refresh bus allows the EDRAM to be refreshed during cache reads.

Memory writes are internally posted in 12ns and directed to the DRAM array. During a write hit, the on-chip address comparator activates a parallel write path to the SRAM cache to maintain

coherency. The EDRAM delivers 12ns cycle page mode memory writes. Memory writes do not affect the contents of the cache row register except during a cache hit.

By integrating the SRAM cache as row registers in the DRAM array and keeping the on-chip control simple, the EDRAM is able to provide superior performance over standard slow 4Mb DRAMs. By eliminating the need for SRAMs and cache controllers, system cost, board space, and power can all be reduced.

Functional Description

The EDRAM is designed to provide optimum memory performance with high speed microprocessors. As a result, it is possible to perform simultaneous operations to the DRAM and SRAM cache sections of the EDRAM. This feature allows the EDRAM to hide precharge and refresh operation during SRAM cache reads and maximize SRAM cache hit rate by maintaining valid cache contents during write operations even if data is written to another memory page. These new functions, in conjunction with the faster basic DRAM and cache speeds of the EDRAM, minimize processor wait states.

EDRAM Basic Operating Modes

The EDRAM operating modes are specified in the table below.

Hit and Miss Terminology

In this datasheet, "hit" and "miss" always refer to a hit or miss to the page of data contained in the SRAM cache row register. This is always equal to the contents of the last row that was read from (as modified by any write hit data). Writing to a new page does not cause the cache to be modified.

DRAM Read Hit

A DRAM read request is initiated by clocking /RE with W/R low and /F & /CAL high. The EDRAM compares the new row address to the last row read address latch (LRR - an 11-bit latch loaded on each /RE active read miss cycle). If the row address matches the LRR, the requested data is already in the SRAM cache and no DRAM memory reference is initiated. The data specified by the column address is available at the output pins at the greater of times t_{AC} or t_{GQV}. Since no DRAM activity is initiated, /RE can be brought high after time t_{RE1}, and a shorter precharge time, t_{RP1}, is allowed. It is possible to access additional SRAM cache locations by providing new column addresses to the multiplex address inputs. New data is available at the output at time t_{AC} after each column address change. During read cycles, it is possible to operate in either static column mode with /CAL=high or page mode with /CAL clocked to latch the column address. In page mode, data valid time is determined by either t_{AC} or t_{CQV}.

DRAM Read Miss

A DRAM read request is initiated by clocking /RE with W/R low and /F & /CAL high. The EDRAM compares the new row address to the LRR address latch (an 11-bit latch loaded on each /RE active read miss cycle). If the row address does not match the LRR, the requested data is not in SRAM cache and a new row must be fetched from the DRAM. The EDRAM will load the new row data into the SRAM cache and update the LRR latch. The data at the specified column address is available at the output pins at the greater of times t_{RAC}, t_{AC}, and t_{GQV}. It is possible to bring /RE high after time t_{RE} since the new row data is safely latched into SRAM cache. This allows the EDRAM to precharge the DRAM array while data is accessed from SRAM cache. It is possible to access additional SRAM cache locations by providing new column addresses to the multiplex address inputs. New data is available at the output at time t_{AC} after each column address change. During read cycles, it is possible to operate in either static column mode with /CAL=high or page mode with /CAL clocked to latch the column address. In page mode, data valid time is determined by either t_{AC} or t_{CQV}.

DRAM Write Hit

If a DRAM write request is initiated by clocking /RE while W/R, /CAL, /WE, and /F are high, the EDRAM will compare the new row address to the LRR address latch (an 11-bit address latch loaded on each /RE active read miss cycle). If the row address matches, the EDRAM will write data to both the DRAM array and selected SRAM cache simultaneously to maintain coherency. The write address and data are posted to the DRAM as soon as the column address is latched by bringing /CAL low and the write data is latched by bringing /WE low. The write address and data can be latched very quickly after the fall of /RE ($t_{RAH} + t_{ASC}$ for the column address and t_{DS} for the data). During a write burst sequence, the second write data can be posted at time t_{RSW} after /RE. Subsequent writes within a page can occur with write cycle time t_{PC}. With /G enabled and /WE disabled, it is possible to perform cache read operations while the /RE is activated in write hit mode. This allows

EDRAM Basic Operating Modes

Function	/S	/RE	W/R	/F	/CAL	/WE	A_{0-10}	Comment
Read Hit	L	↓	L	H	H	X	Row = LRR	No DRAM Reference, Data in Cache
Read Miss	L	↓	L	H	H	X	Row ≠ LRR	DRAM Row to Cache
Write Hit	L	↓	H	H	H	H	Row = LRR	Write to DRAM and Cache, Reads Enabled
Write Miss	L	↓	H	H	H	H	Row ≠ LRR	Write to DRAM, Cache Not Updated, Reads Disabled
Internal Refresh	X	↓	X	L	X	X	X	Cache Reads Enabled
Low Power Standby	H	H	X	X	H	H	X	1mA Standby Current
Unallowed Mode	H	L	X	H	X	X	X	Unallowed Mode (Except -L Option)
Low Power Self-Refresh Option	H	↓	H	H	L	H	X	Standby Current, Internal Refresh Clock (-L Option)

H = High; L = Low; X = Don't Care; ↓ = High-to-Low Transition; LRR = Last Row Read

read-modify-write, write-verify, or random read-write sequences within the page with 12ns cycle times (the first read cannot complete until after time t_{RAC2}). At the end of a write sequence (after /CAL and /WE are brought high and t_{RE} is satisfied), /RE can be brought high to precharge the memory. It is possible to perform cache reads concurrently with precharge. During write sequences, a write operation is not performed unless both /CAL and /WE are low. As a result, the /CAL input can be used as a byte write select in multi-chip systems. If /CAL is not clocked on a write sequence, the memory will perform a /RE only refresh to the selected row and data will remain unmodified.

DRAM Write Miss

If a DRAM write request is initiated by clocking /RE while W/R, /CAL, /WE, and /F are high, the EDRAM will compare the new row address to the LRR address latch (an 11-bit latch loaded on each /RE active read miss cycle). If the row address does not match, the EDRAM will write data to the DRAM array only and contents of the current cache are not modified. The write address and data are posted to the DRAM as soon as the column address is latched by bringing /CAL low and the write data is latched by bringing /WE low. The write address and data can be latched very quickly after the fall of /RE (t_{RAH} + t_{ASC} for the column address and t_{DS} for the data). During a write burst sequence, the second write data can be posted at time t_{RSW} after /RE. Subsequent writes within a page can occur with write cycle time t_{PC}. During a write miss sequence, cache reads are inhibited and the output buffers are disabled (independently of /G) until time t_{WRR} after /RE goes high. At the end of a write sequence (after /CAL and /WE are brought high and t_{RE} is satisfied), /RE can be brought high to precharge the memory. It is possible to perform cache reads concurrently with the precharge. During write sequences, a write operation is not performed unless both /CAL and /WE are low. As a result, /CAL can be used as a byte write select in multi-chip systems. If /CAL is not clocked on a write sequence, the memory will perform a /RE only refresh to the selected row and data will remain unmodified.

/RE Inactive Operation

It is possible to read data from the SRAM cache without clocking /RE. This option is desirable when the external control logic is capable of fast hit/miss comparison. In this case, the controller can avoid the time required to perform row/column multiplexing on hit cycles. This capability also allows the EDRAM to perform cache read operations during precharge and refresh cycles to minimize wait states and reduce power. It is only necessary to select /S and /G and provide the appropriate column address to read data as shown in the table below. The row address of the SRAM cache accessed without clocking /RE will be specified by the LRR address latch loaded during the last /RE active read cycle. To perform a cache read in static column mode, /CAL is held high, and the cache contents at the specified column address will be valid at time t_{AC} after address is stable. To perform a cache read in page mode,

Function	*/S*	*/G*	*/CAL*	A_{0-8}
Cache Read (Static Column)	L	L	H	Column Address
Cache Read (Page Mode)	L	L	↓	Column Address

H = High; L = Low; X = Don't Care; ↓ = Transitioning

/CAL is clocked to latch the column address. The cache data is valid at time t_{AC} after the column address is setup to /CAL.

Internal Refresh

If /F is active (low) on the assertion of /RE, an internal refresh cycle is executed. This cycle refreshes the row address supplied by an internal refresh counter. This counter is incremented at the end of the cycle in preparation for the next /F refresh cycle. At least 1,024 /F cycles must be executed every 64ms. /F refresh cycles can be hidden because cache memory can be read under column address control throughout the entire /F cycle.

Low Power Mode

The EDRAM enters its low power mode when /S is high. In this mode, the internal DRAM circuitry is powered down to reduce standby current to 1mA.

Low Power, Self-Refresh Option

When the low power, self refresh mode option is specified when ordering the EDRAM, the EDRAM enters this mode when /RE is clocked while /S, W/R, /F, and /WE are high; and /CAL is low. In this mode, the power is turned off to all I/O pins except /RE to minimize chip power, and an on-board refresh clock is enabled to perform self-refresh cycles using the on-board refresh counter. The EDRAM remains in this low power mode until /RE is brought high again to terminate the mode. The EDRAM /RE input must remain high for t_{RP2} following exit from self-refresh mode to allow any on-going internal refresh to terminate prior to the next memory operation.

Write-Per-Bit Operation

The DM2212 version of the 1Mb x 4 EDRAM offers a write-per-bit capability which allows single bits of the memory to be selectively written without altering other bits in the same word. This capability may be useful for implementing parity or masking data in video graphics applications. The bits to be written are determined by a bit mask data word which is placed on the I/O data pins DQ_{0-3} prior to clocking /RE. The logic one bits in the mask data select the bits to be written. As soon as the mask is latched by /RE, the mask data is removed and write data can be placed on the databus. The mask is only specified on the /RE transition. During page mode burst write operations, the same mask is used for all write operations.

+3.3 Volt Power Supply Operation

If the +3.3 volt power supply option is specified, the EDRAM will operate from a +3.3 volt ±0.3 volt power supply and all inputs and outputs will have LVTTL/LVCMOS compatible signal levels. The +3.3 volt EDRAM will not accept input levels which exceed the power supply voltage. If mixed I/O levels are expected in your system, please specify the +5 volt version of the EDRAM.

/CAL Before /RE Refresh ("/CAS Before /RAS")

/CAL before /RE refresh, a special case of internal refresh, is discussed in the "Reduced Pin Count Operation" section below.

/RE Only Refresh Operation

Although /F refresh using the internal refresh counter is the recommended method of EDRAM refresh, it is possible to perform an /RE only refresh using an externally supplied row address. /RE refresh is performed by executing a *write cycle* (W/R and /F are high) where /CAL is not clocked. This is necessary so that the current cache contents and LRR are not modified by the refresh operation. All combinations of addresses A_{0-9} must be sequenced every 64ms refresh period. A_{10} does not need to be cycled. Read refresh cycles

are not allowed because a DRAM refresh cycle does not occur when a read refresh address matches the LRR address latch.

Initialization Cycles

A minimum of 10 initialization (start-up) cycles are required before normal operation is guaranteed. At least eight /F refresh cycles and two read cycles to different row addresses are necessary to complete initialization. /RE must be high for at least 300ns prior to initialization.

Unallowed Mode

Read, write, or /RE only refresh operations must not be performed to unselected memory banks by clocking /RE when /S is high.

Reduced Pin Count Operation

Although it is desirable to use all EDRAM control pins to optimize system performance, it is possible to simplify the interface to the EDRAM by either tying pins to ground or by tying one or more control inputs together. The /S input can be tied to ground if the low power standby modes are not required. The /CAL and /F pins can be tied together if hidden refresh operation is not required. In this case, a CBR refresh (/CAL before /RE) can be performed by holding the combined input low prior to /RE. A CBR refresh does not require that a row address be supplied when /RE is asserted. The timing is identical to /F refresh cycle timing. The /WE input can be tied to /CAL if independent posting of column addresses and data are not required during write operations. In this case, both column address and write data will be latched by the combined input during writes. W/R and /G can be tied together if reads are not performed during write hit cycles. If these techniques are used, the EDRAM will require only three control lines for operation (/RE, /CAS [combined /CAL, /F, and /WE], and W/R [combined W/R and /G]). The simplified control interface still allows the fast page read/write cycle times, fast random read/write times, and hidden precharge functions available with the EDRAM.

Pin Descriptions

/RE — Row Enable

This input is used to initiate DRAM read and write operations and latch a row address. It is not necessary to clock /RE to read data from the EDRAM SRAM row registers. On read operations, /RE can be brought high as soon as data is loaded into cache to allow early precharge.

/CAL — Column Address Latch

This input is used to latch the column address and in combination with /WE to trigger write operations. When /CAL is high, the column address latch is transparent. When /CAL is low, the column address latch is closed and the output of the latch contains the address present while /CAL was high.

W/R — Write/Read

This input along with /F specifies the type of DRAM operation initiated on the low going edge of /RE. When /F is high, W/R specifies either a write (logic high) or read operation (logic low).

/F — Refresh

This input will initiate a DRAM refresh operation using the internal refresh counter as an address source when it is low on the low going edge of /RE.

/WE — Write Enable

This input controls the latching of write data on the input data pins. A write operation is initiated when both /CAL and /WE are low.

/G — Output Enable

This input controls the gating of read data to the output data pins during read operations.

/S — Chip Select

This input is used to power up the I/O and clock circuitry. When /S is high, the EDRAM remains in its low power mode. /S must remain active throughout any read or write operation. With the exception of /F refresh cycles, /RE should never be clocked when /S is inactive.

DQ_{0-3} — Data Input/Output

These bidirectional data pins are used to read and write data to the EDRAM. On the DM2212 write-per-bit memory, these pins are also used to specify the bit mask used during write operations.

A_{0-10} — Multiplex Address

These inputs are used to specify the row and column addresses of the EDRAM data. The 11-bit row address is latched on the falling edge of /RE. The 9-bit column address can be specified at any other time to select read data from the SRAM cache or to specify the write column address during write cycles.

V_{CC} Power Supply

These inputs are connected to the +5 or +3.3 volt power supply.

V_{SS} Ground

These inputs are connected to the power supply ground connection.

Pin Names

Pin Names	Function
A_{0-10}	Address Inputs
/RE	Row Enable
DQ_{0-3}	Data In/Data Out
/CAL	Column Address Latch
W/R	Write/Read Control
V_{CC}	Power (+5V or +3.3V)

Pin Names	Function
V_{SS}	Ground
/WE	Write Enable
/G	Output Enable
/F	Refresh Control
/S	Chip Select - Active/Standby Control
NC	Not Connected

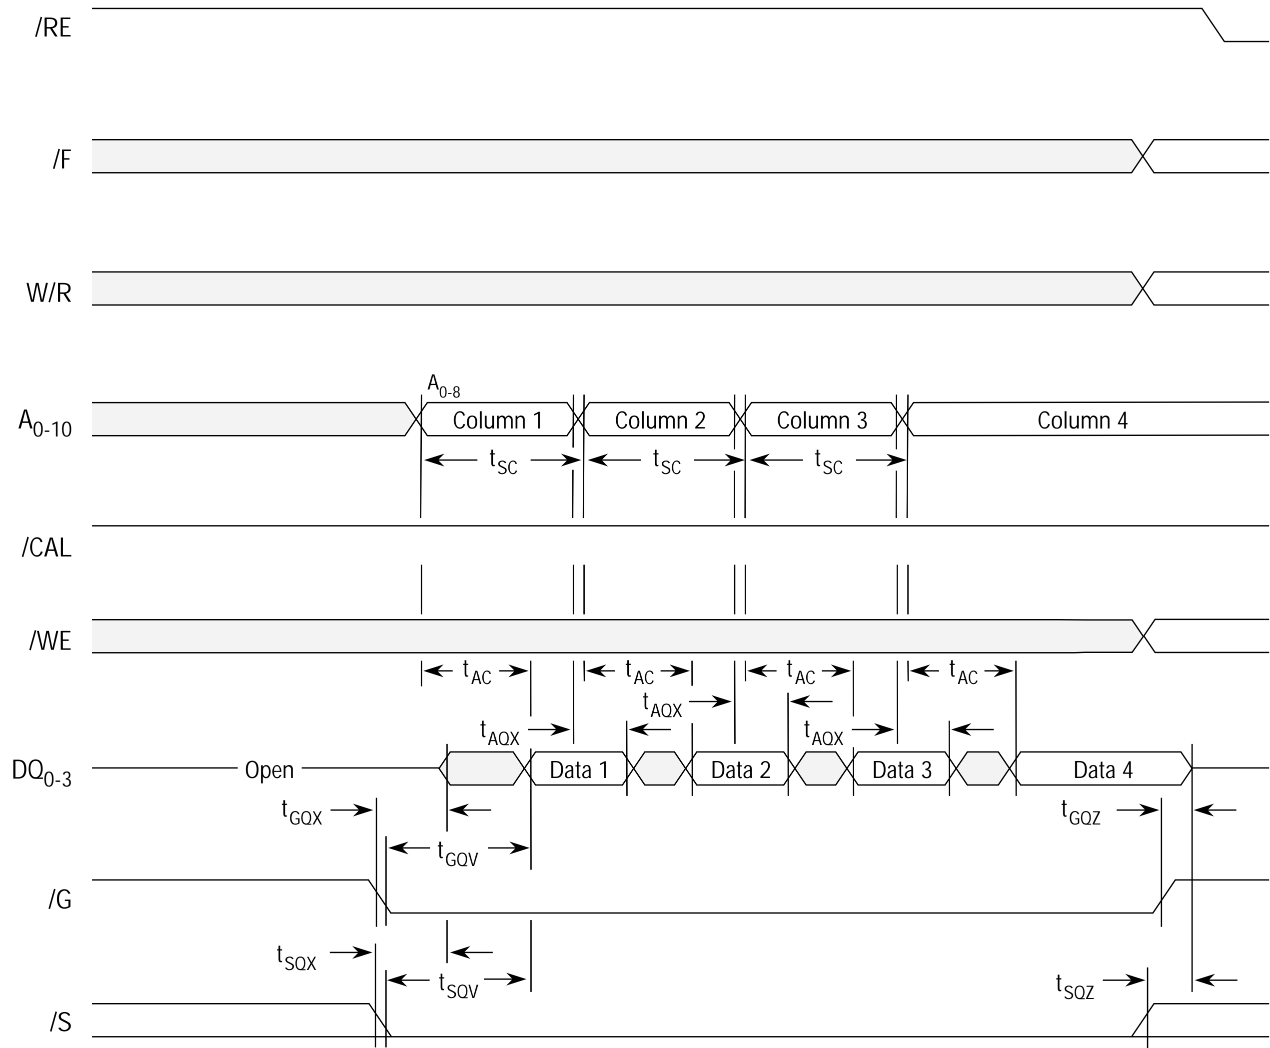
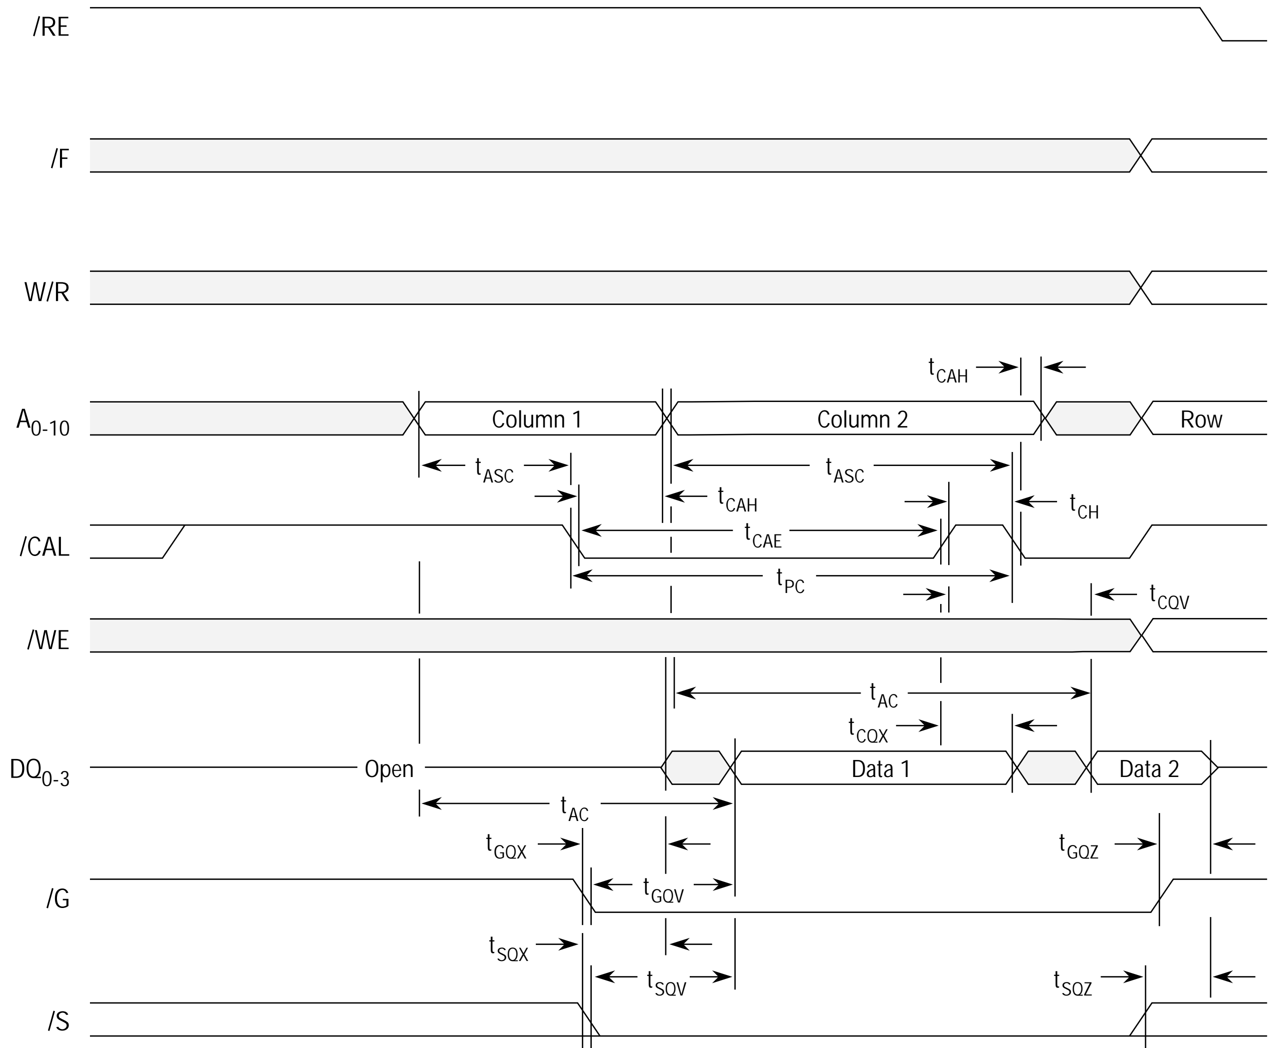
(1) V_{OUT} Timing Reference Point at 1.5V
(2) Parameter Defines Time When Output is Enabled (Sourcing or Sinking Current) and is Not Referenced to V_{OH} or V_{OL}
(3) Minimum Specification is Referenced from V_{IH} and Maximum Specification is Referenced from V_{IL} on Input Control Signal
(4) Parameter Defines Time When Output Achieves Open-Circuit Condition and is Not Referenced to V_{OH} or V_{OL}
(5) Minimum Specification is Referenced from V_{IL} and Maximum Specification is Referenced from V_{IH} on Input Control Signal
(6) Access Parameter Applies When /CAL Has Not Been Asserted Prior to t_{RAC2}
(7) For Write-Per-Bit Devices, t_{WHR} is Limited By Data Input Setup Time, t_{DS}

/RE Inactive Cache Read Hit (Static Column Mode)



NOTES: 1. Data accessed during /RE inactive read is from the row address specified during the last /RE active read cycle.

/RE Inactive Cache Read Hit (Page Mode)



NOTES: 1. Data accessed during /RE inactive read is from the row address specified during the last /RE active read cycle.

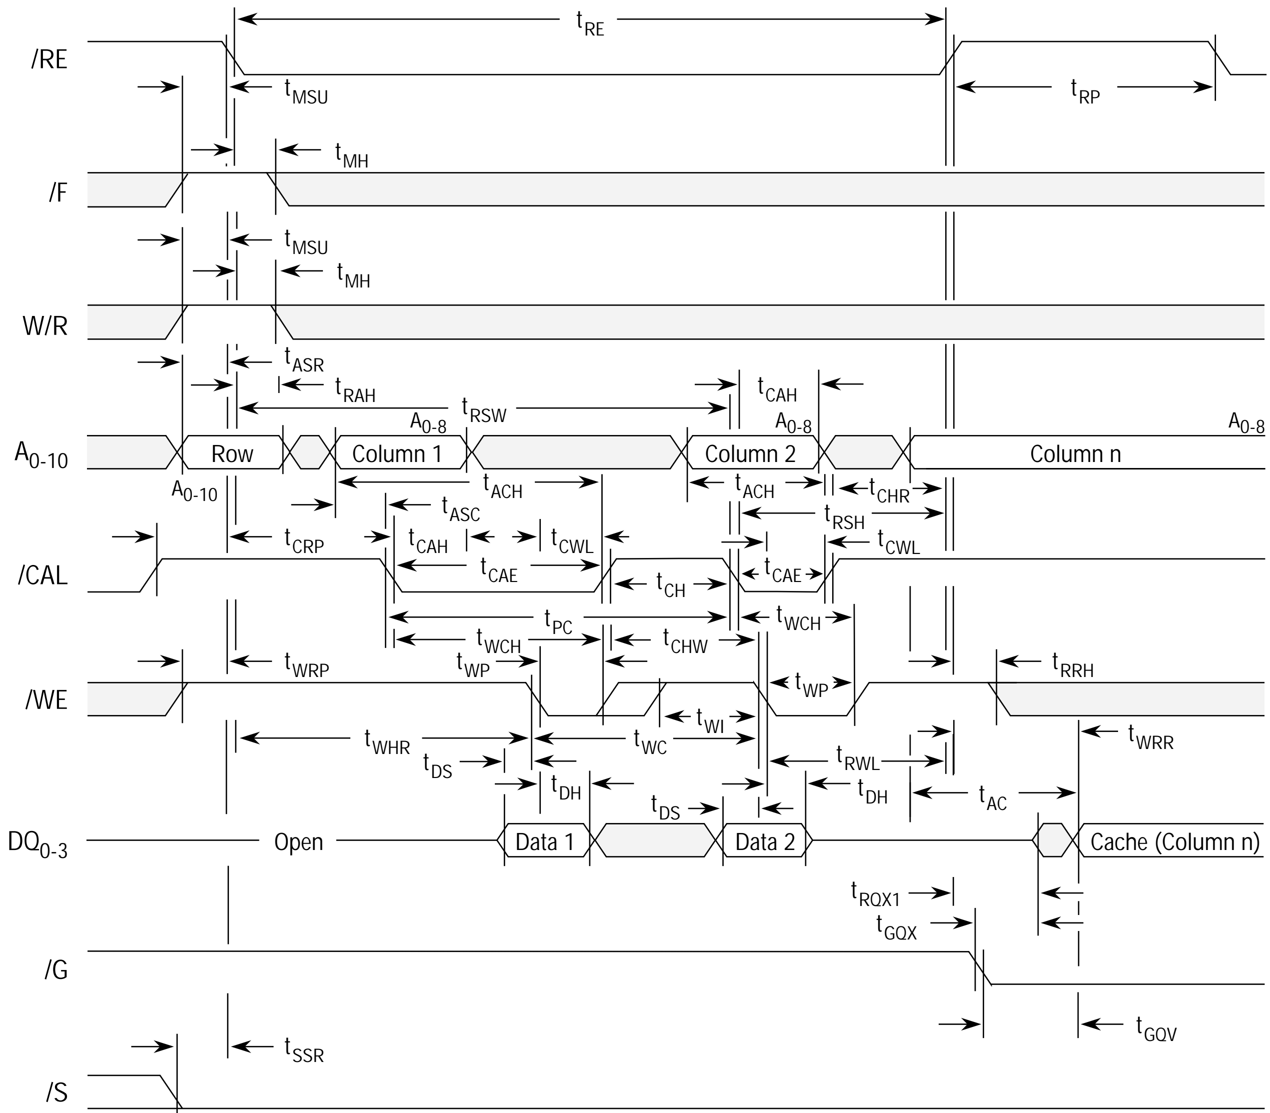
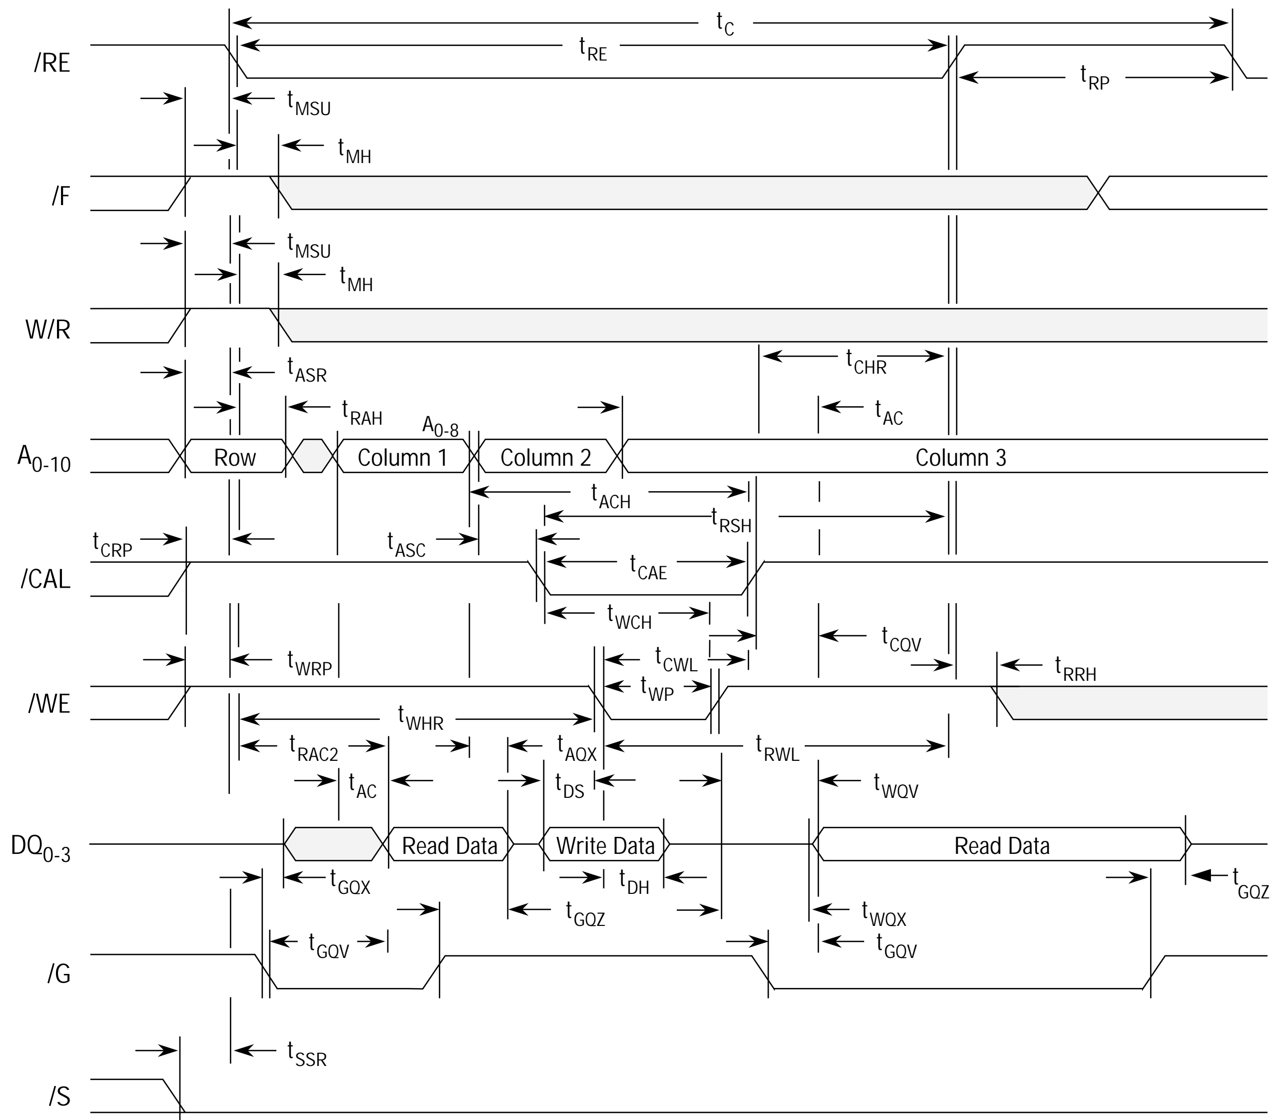
Don't Care or Indeterminate

Burst Write (Hit or Miss) Followed By /RE Inactive Cache Reads



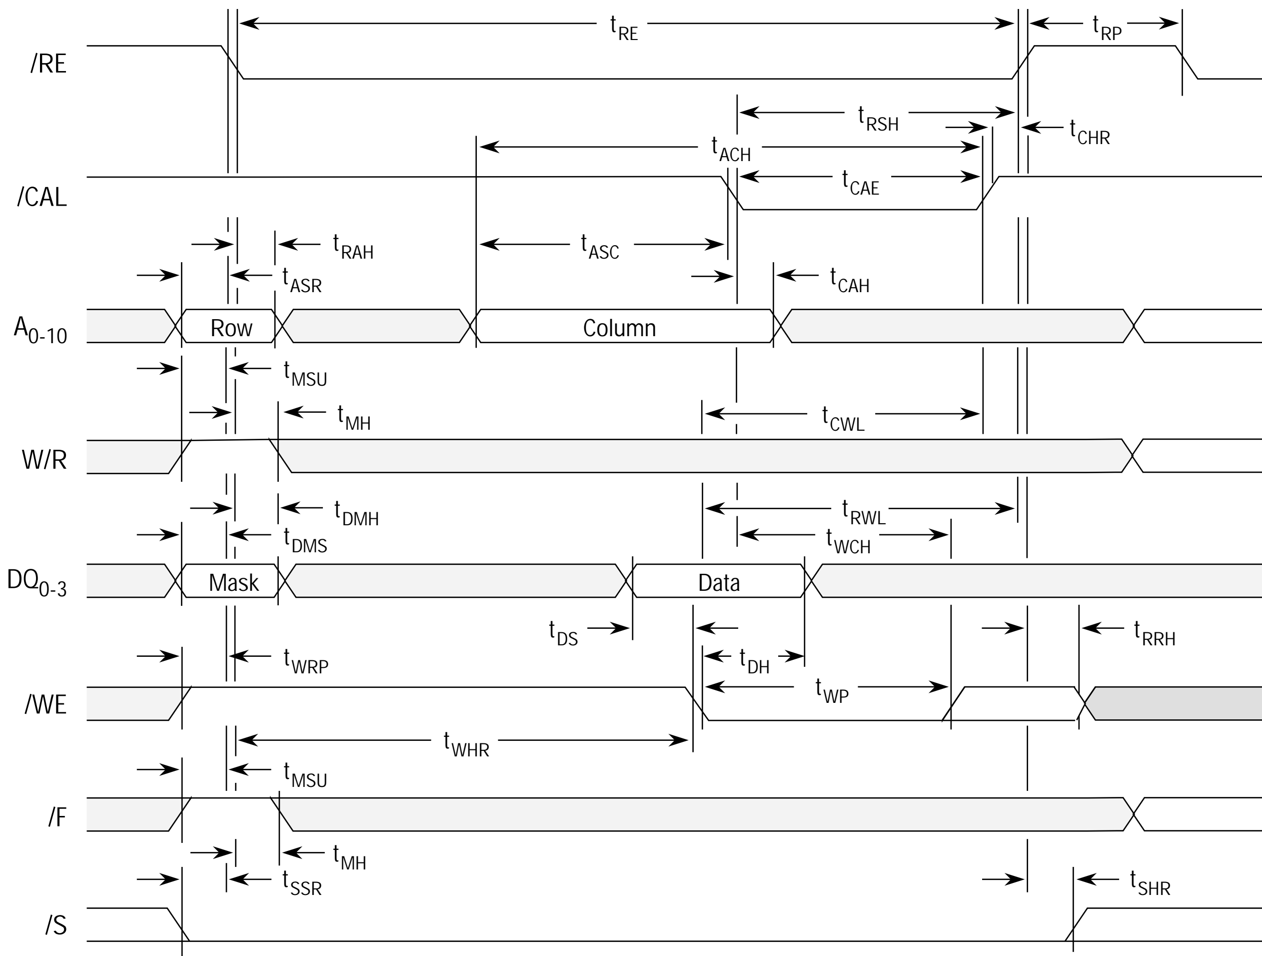
NOTES: 1. /G becomes a don't care after t_{RGX} during a write miss.

Read/Write During Write Hit Cycle (Can Include Read-Modify-Write)



NOTES: 1. If column address one equals column address two, then a read-modify-write cycle is performed.

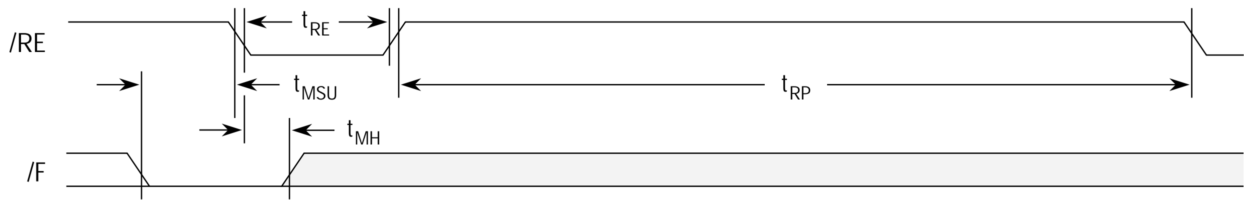
Write-Per-Bit Cycle (/G=High)



NOTES: 1. Data mask bit high (1) enables bit write; data mask bit low (0) inhibits bit write.

2. Write-per-bit cycle valid only for DM2212.

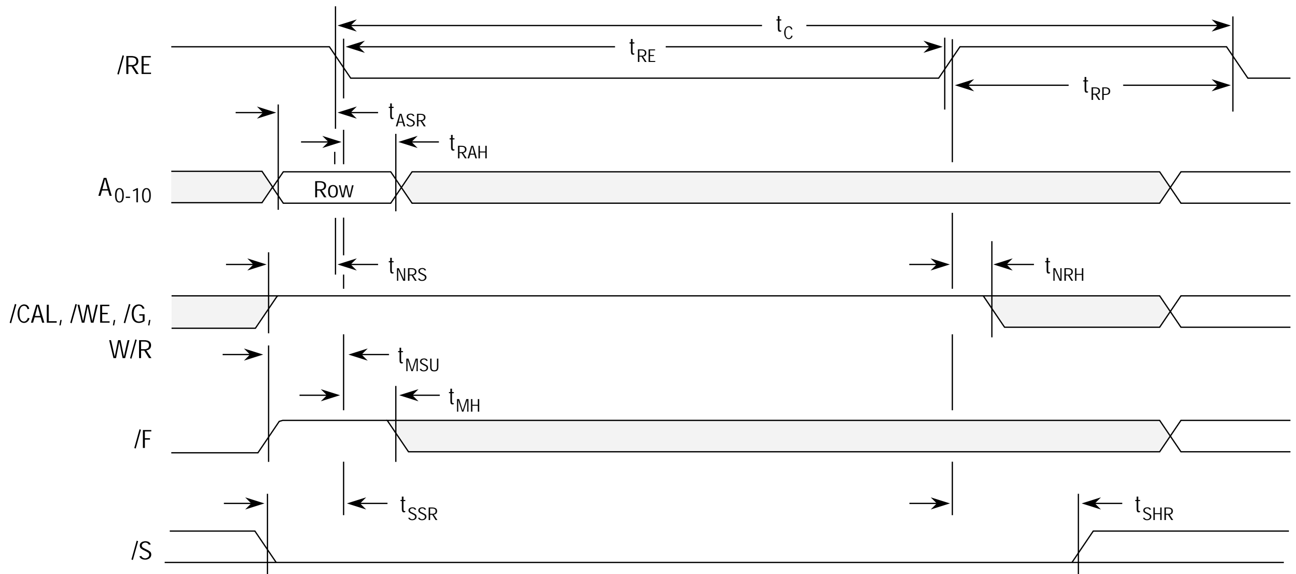
/F Refresh Cycle



Don't Care or Indeterminate

NOTES: 1. During /F refresh cycles, the status of W/R, /WE, A_{0-10}, /CAL, /S, and /G is a don't care.
2. /RE inactive cache reads may be performed in parallel with /F refresh cycles.

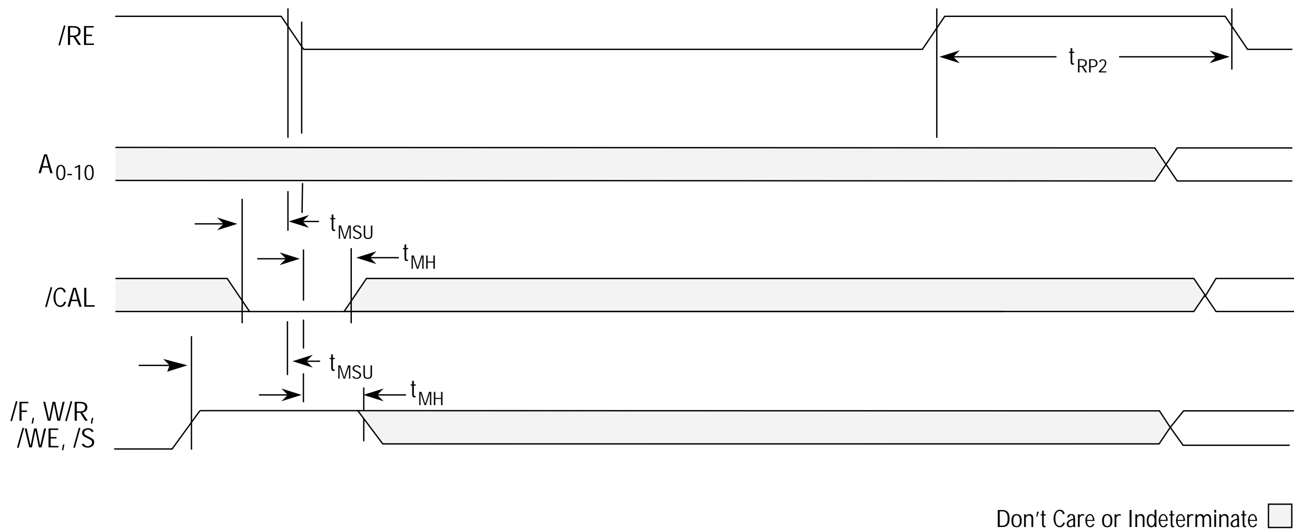
/RE-Only Refresh



Don't Care or Indeterminate

NOTES: 1. All binary combinations of A_{0-9} must be refreshed every 64ms interval. A_{10} does not have to be cycled, but must remain valid during row address setup and hold times.
2. /RE refresh is write cycle with no /CAL active cycle.

Low Power Self-Refresh Mode Option



NOTES: 1. EDRAM self refreshes as long as /RE remains low. (Low Power Self Refresh part only).
2. When using the Low Power Self Refresh mode the following operations must be performed:
If row addresses are being refreshed in an *evenly distributed* manner over the refresh interval using /F refresh cycles, then at least one /F refresh cycle must be performed immediately after exit from the Low Power Self Refesh Mode. If row addresses are being refreshed in any other manner (/F burst or /RE distributed or burst), then all rows must be refreshed immediately befor entry to and immediately after exit from the Low Power Self Refresh.
