

■ OUTLINE

The R1225N Series are CMOS-based PWM step-down DC/DC Converter controllers with low supply current.

Each of these ICs consists of an oscillator, a PWM control circuit, a reference voltage unit, an error amplifier, a soft-start circuit, a latch-type protection circuit, a PWM/VFM alternative circuit, a chip enable circuit, a phase compensation circuit, and an input voltage detect circuit. Further, protection circuit delay time adjuster circuit, and resistors for voltage detection are included. A low ripple, high efficiency step-down DC/DC converter can be easily composed of this IC with some external components, or a power-transistor, an inductor, a diode and capacitors.

With a PWM/VFM alternative circuit, when the load current is small, the operation is automatically switching into the VFM oscillator from PWM oscillator, therefore the efficiency at small load current is improved. The R1225NXXXC/D/K types, which are without a PWM/VFM alternative circuit, are also available.

If the term of maximum duty cycle keeps on a certain time, the embedded protection circuit works. It is latch-type protection circuit, and it works to latch an external Power MOSFET with keeping it off. To release the condition of protection, after disable this IC with a chip enable circuit, enable it again, or restart this IC with power-on. Delay Time for protection circuit is adjustable with an external capacitor. With a built-in UVLO function, when the input voltage is UVLO threshold or less, this IC keeps standby state, and saves its consumption current and avoids miss-operation. Further, if the set output voltage is equal or more than 2.1V, with a built-in start-up function, at the power-on moment until the input voltage becomes more than the set output voltage, DC/DC operation is halted and avoids miss-operation.

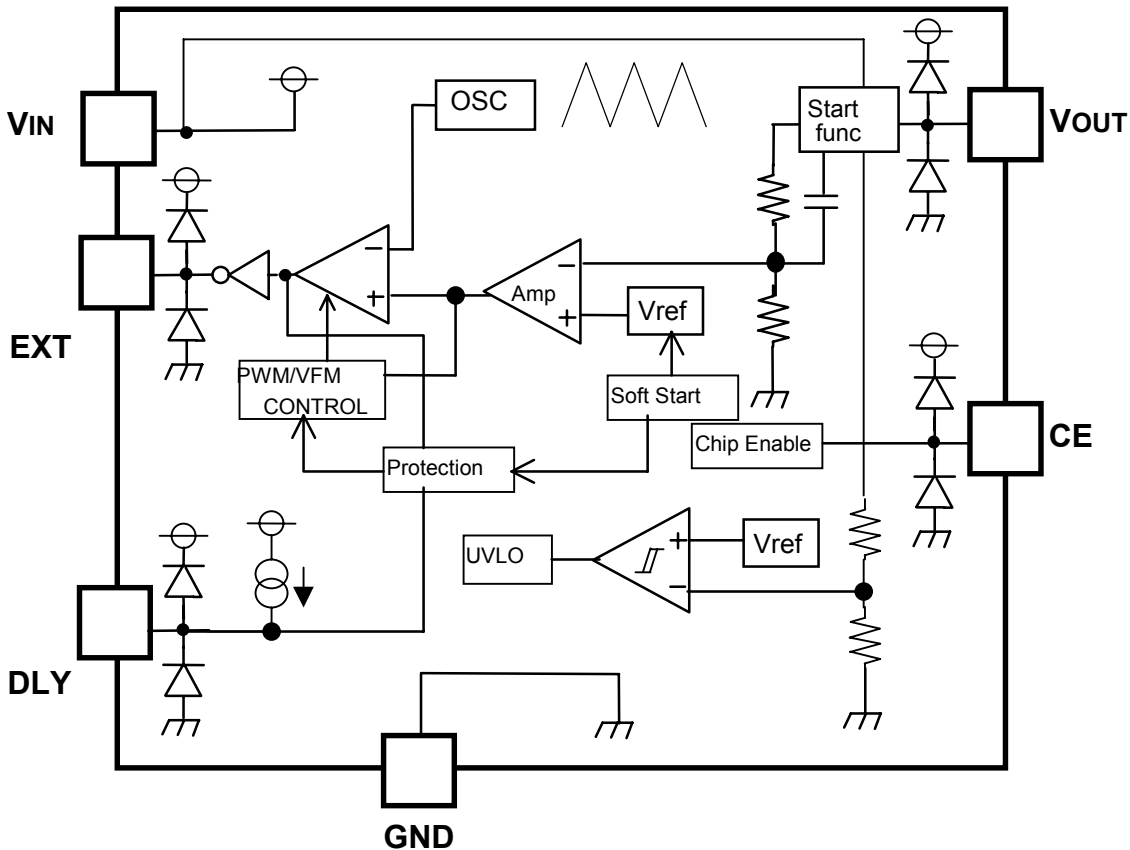

■ FEATURES

- Wide Range of Input Voltage2.3V~18.5V
- Built-in Soft-start Function and Latch-type Protection Function
- Three options of Oscillator Frequency180kHz, 300kHz, 500kHz
- High EfficiencyTyp. 90%
- Output VoltageStepwise Setting with a step of 0.1V in the range of 1.2V ~ 6.0V
- Standby CurrentTyp. 0.0μA
- High Accuracy Output Voltage±2.0%
- Low Temperature-Drift Coefficient of Output Voltage Typ. ±100ppm/°C

■ APPLICATIONS

- Power source for hand-held communication equipment, cameras, video instruments such as VCRs, camcorders.
- Power source for battery-powered equipment.
- Power source for household electrical appliances.

■ BLOCK DIAGRAM

■ SELECTION GUIDE

In the R1225N Series, the output voltage, the oscillator frequency, the optional function, and the taping type for the ICs can be selected at the user's request.

The selection can be made with designating the part number as shown below;

R1225NXX2X-TR

↑ ↑ ↑ ↑
a b c d

Code	Contents
a	Setting Output Voltage(VOUT): Stepwise setting with a step of 0.1V in the range of 1.2V to 6.0V is possible.
b	Designation of Oscillator Frequency 2 : fixed
c	Designation of Optional Function A : 300kHz, with a PWM/VFM alternative circuit B : 500 kHz, with a PWM/VFM alternative circuit C : 300kHz, without a PWM/VFM alternative circuit D : 500kHz, without a PWM/VFM alternative circuit J : 180kHz, with a PWM/VFM alternative circuit K : 180 kHz, without a PWM/VFM alternative circuit
d	Designation of Taping Type: Refer to Taping specification. "TR" is prescribed as a standard.

■ PIN CONFIGURATION

● SOT-23-6W

■ PIN DESCRIPTION

Pin No.	Symbol	Description
1	EXT	External Transistor Drive Pin(CMOS Output Type)
2	VIN	Power Supply Pin
3	DLY	Pin for Setting External Capacitor for Protection Circuit Delay Time
4	CE	Chip Enable Pin (Active "H")
5	GND	Ground Pin
6	VOUT	Pin for Monitoring Output Voltage

■ ABSOLUTE MAXIMUM RATINGS

Symbol	Item	Rating	Unit
VIN	VIN Supply Voltage	20	V
VEXT	EXT Pin Output Voltage	-0.3~VIN+0.3	V
VCE	CE Pin Input Voltage	-0.3~VIN+0.3	V
VOUT	VOUT Pin Input Voltage	-0.3~VIN+0.3	V
VDLY	VDLY Pin Input Voltage	-0.3~+1.0	V
IEXT	EXT Pin Inductor Drive Output Current	±50	mA
IDLY	DLY Pin Output Current	±15	mA
PD	Power Dissipation	250	mW
Topt	Operating Temperature Range	-40~+85	°C
Tstg	Storage Temperature Range	-55~+125	°C

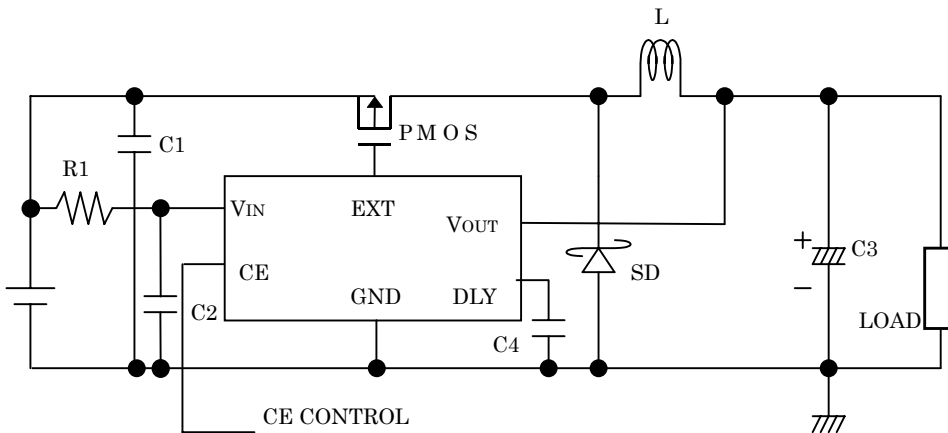

■ ELECTRICAL CHARACTERISTICS

■ TYPICAL APPLICATION AND APPLICATION HINTS

PMOS: HAT1044M (Hitachi) L: CR105-270MC (Sumida, 27 μ H)
SD1 : RB063L-30 (Rohm) C3: 47 μ F (Tantalum Type)
C1 : 10 μ F (Ceramic Capacitor) C2: 0.1 μ F (Ceramic Capacitor) C4: 20nF (Ceramic Capacitor)
R1 : 10 Ω

When you use these ICs, consider the following issues;

- As shown in the block diagram, a parasitic diode is formed in each terminal, each of these diodes is not formed for load current, therefore do not use it in such a way. When you control the CE pin by another power supply, do not make its "H" level more than the voltage level of VIN pin.

- The operation of Latch-type protection circuit is as follows;

When the maximum duty cycle continues longer than the delay time for protection circuit, (Refer to the Electrical Characteristics) the protection circuit works to shutdown Power MOSFET with latching operation. Therefore when an input/output voltage difference is small, the protection circuit may work with small load current.

To release the protection of latch status, after disable this IC with a chip enable circuit, enable it again, or restart this IC with power-on. However, in the case of restarting this IC with power-on, after the power supply is turned off, if a certain amount of charge remains in CIN, or some voltage is forced to VIN from CIN, this IC might not be restarted even after power-on.

- Set external components as close as possible to the IC and minimize the connection between the components and the IC. In particular, a capacitor should be connected to VOUT pin with the minimum connection. Make grounding sufficient and reinforce supplying. Large switching current flows through the connection of power line, an inductor and the connection of VOUT. If the impedance of the connection of power supply is high, the voltage level of power supply of the IC fluctuates with the switching current. This may cause unstable operation of the IC.

- Use capacitors with a capacity of 22 μ F or more for VOUT pin, and with good high frequency characteristics such as tantalum capacitors. We recommend to use capacitors with an allowable voltage which is at least twice as much as setting output voltage, in terms of the input capacitors, its voltage rating is twice or more than input voltage. This is because there may be a case where a spike-shaped high voltage is generated by an inductor when an external transistor is on and off.

- Choose an inductor that has sufficiently small D.C. resistance and large allowable current and is hard to reach magnetic saturation. If the value of inductance of an inductor is extremely small, the ILX may exceed the absolute maximum rating at the maximum loading. Use an inductor with appropriate inductance.

- Use a diode of a Schottky type with high switching speed, and also pay attention to its current capacity.

- Do not use this IC under the condition with VIN voltage at equal or less than minimum operating

voltage.

● When the threshold level of an external power MOSFET is rather low and the drive-ability of voltage supplier is small, if the output pin is short circuit, input voltage may be equal or less than UVLO detector threshold. In this case, the device is reset with UVLO function that is not the latch-protection function.

● With the PWM/VFM alternative circuit, when the on duty cycle of switching is 35% or less, the R1225N alters from PWM mode to VFM mode (Pulse skip mode). The purpose of this circuit is raising the efficiency with a light load by skipping the frequency and suppressing the consumption current. However, the ratio of output voltage against input voltage is 35% or less, (ex. $V_{in} > 8.6V$ and $V_{out} = 3.0V$) even if the large current may be loaded, the IC keeps its VFM mode. As a result, frequency might be decreased, and oscillation waveform might be unstable. These phenomena are the typical characteristics of the IC with PWM/VFM alternative circuit.

☆ The performance of power source circuits using these ICs extremely depends upon the peripheral circuits.

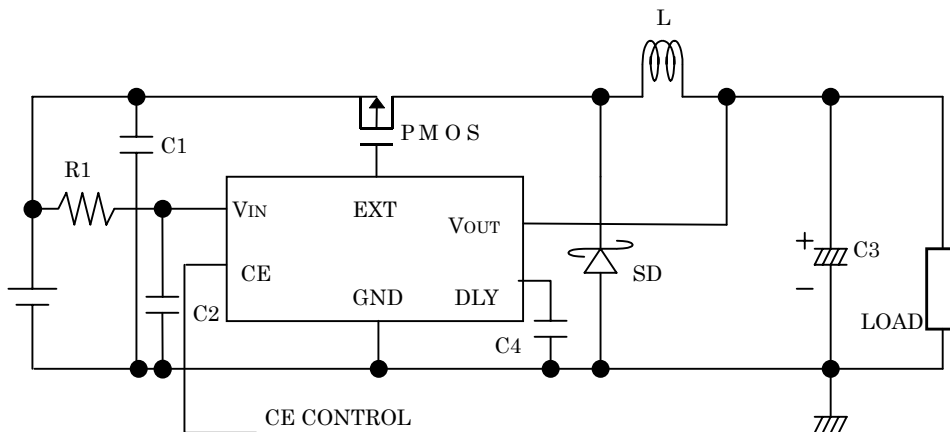

Pay attention in the selection of the peripheral circuits. In particular, design the peripheral circuits in a way that the values such as voltage, current, and power of each component, PCB patterns and the IC do not exceed their respected rated values.

■ How to set the delay time of protection circuit

The equation describes how to calculate the delay time of protection circuit from the value of an external capacitor C4.

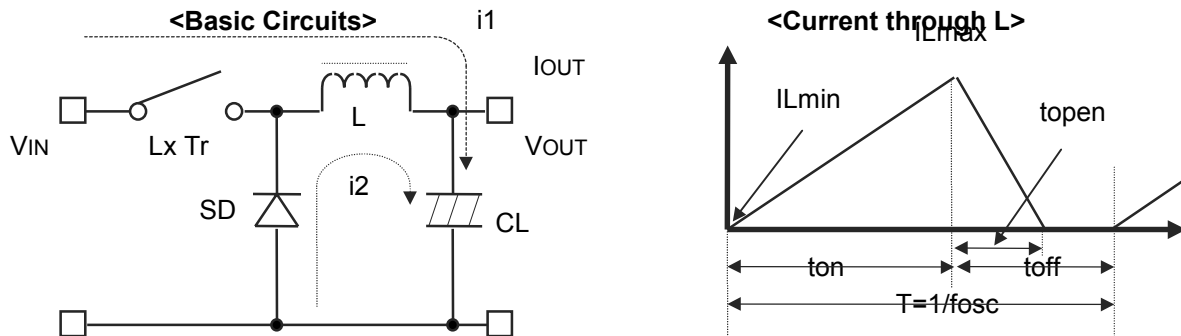

$$TDLY = C4 \times 10^6 \text{ sec (In this equation, } 1000\text{pF} \leq C4 \leq 1\mu\text{F)}$$

Without the external capacitor, a certain delay time exists, therefore, if the external capacitor is less than 1000pF, the error will increase. Further, if the external capacitor value is beyond 1μF, the time required to discharge the C4 will be long, and this may cause the miss-operation. For example, if the protection circuit may work and released, soon after that the protection may work. In that case, C4 has not discharged completely yet, therefore, the delay time may be shorter than expected.

■ OPERATION of step-down DC/DC converter and Output Current

The step-down DC/DC converter charges energy in the inductor when Lx transistor is ON, and discharges the energy from the inductor when Lx transistor is OFF and controls with less energy loss, so that a lower output voltage than the input voltage is obtained. The operation will be explained with reference to the following diagrams:

Step 1: Lx Tr. turns on and current $I_L (=i_1)$ flows, and energy is charged into CL. At this moment, I_L increases from $I_{Lmin} (=0)$ to reach I_{Lmax} in proportion to the on-time period (t_{on}) of LX Tr.

Step 2: When Lx Tr. turns off, Schottky diode (SD) turns on in order that L maintains I_L at I_{Lmax} , and current $I_L (=i_2)$ flows.

Step 3: I_L decreases gradually and reaches I_{Lmin} after a time period of t_{open} , and SD turns off, provided that in the continuous mode, next cycle starts before I_L becomes to 0 because t_{off} time is not enough. In this case, I_L value is from this $I_{Lmin} (>0)$.

In the case of PWM control system, the output voltage is maintained by controlling the on-time period (t_{on}), with the oscillator frequency (f_{osc}) being maintained constant.

● Discontinuous Conduction Mode and Continuous Conduction Mode

The maximum value (I_{Lmax}) and the minimum value (I_{Lmin}) current which flow through the inductor is the same as those when Lx Tr. turns on and when it turns off.

The difference between I_{Lmax} and I_{Lmin} , which is represented by ΔI ;

$$\Delta I = I_{Lmax} - I_{Lmin} = V_{OUT} \times t_{open} / L = (V_{IN} - V_{OUT}) \times t_{on} / L \dots \text{Equation 1}$$

Where, $T = 1/f_{osc} = t_{on} + t_{off}$

$$\text{duty (\%)} = t_{on} / T \times 100 = t_{on} \times f_{osc} \times 100$$

$$t_{open} \leq t_{off}$$

In Equation 1, $V_{OUT} \times t_{open} / L$ and $(V_{IN} - V_{OUT}) \times t_{on} / L$ are respectively shown the change of the current at ON, and the change of the current at OFF.

When the output current (I_{OUT}) is relatively small, $t_{open} < t_{off}$ as illustrated in the above diagram. In this case, the energy is charged in the inductor during the time period of t_{on} and is discharged in its entirety during the time period of t_{off} , therefore I_{Lmin} becomes to zero ($I_{Lmin} = 0$). When I_{OUT} is gradually increased, eventually, t_{open} becomes to t_{off} ($t_{open} = t_{off}$), and when I_{OUT} is further increased, I_{Lmin} becomes larger than zero ($I_{Lmin} > 0$). The former mode is referred to as the discontinuous mode and the latter mode is referred to as continuous mode.

In the continuous mode, when Equation 1 is solved for t_{on} and assumed that the solution is t_{onc} ,

$$t_{onc} = T \times V_{OUT} / V_{IN} \dots \text{Equation 2}$$

When $t_{on} < t_{onc}$, the mode is the discontinuous mode, and when $t_{on} = t_{onc}$, the mode is the continuous mode.

■ OUTPUT CURRENT AND SELECTION OF EXTERNAL COMPONENTS

When Lx Tr. is "ON":

(Wherein, Ripple Current P-P value is described as I_{RP} , ON resistance of LX Tr. is described as R_p the

direct current of the inductor is described as I_{L} .)

$$V_{IN} = V_{OUT} + (R_p + R_L) \times I_{OUT} + L \times I_{RP} / t_{ON} \dots \text{Equation 3}$$

When L_x Tr. is "OFF":

$$L \times I_{RP} / t_{OFF} = V_F + V_{OUT} + R_L \times I_{OUT} \dots \text{Equation 4}$$

Put Equation 4 to Equation 3 and solve for ON duty, $t_{ON} / (t_{OFF} + t_{ON}) = D_{ON}$,

$$D_{ON} = (V_{OUT} + V_F + R_L \times I_{OUT}) / (V_{IN} + V_F - R_p \times I_{OUT}) \dots \text{Equation 5}$$

Ripple Current is as follows;

$$I_{RP} = (V_{IN} - V_{OUT} - R_p \times I_{OUT} - R_L \times I_{OUT}) \times D_{ON} / f / L \dots \text{Equation 6}$$

Wherein, peak current that flows through L , L_x Tr., and SD is as follows;

$$I_{Lmax} = I_{OUT} + I_{RP} / 2 \dots \text{Equation 7}$$

Consider I_{Lmax} , condition of input and output and select external components.

★The above explanation is directed to the calculation in an ideal case in continuous mode.

■ External Components

1. Inductor

Select an inductor that peak current does not exceed I_{Lmax} . If larger current than allowable current flows, magnetic saturation occurs and make transform efficiency worse.

When the load current is definite, the smaller value of L , the larger the ripple current.

Provided that the allowable current is large in that case and DC current is small, therefore, for large output current, efficiency is better than using an inductor with a large value of L and vice versa.

2. Diode

Use a diode with low V_F (Schottky type is recommended.) and high switching speed.

Reverse voltage rating should be more than V_{IN} and current rating should be equal or more than I_{Lmax} .

3. Capacitors

As for C_{IN} , use a capacitor with low ESR (Equivalent Series Resistance) and a capacity of at least $10\mu F$ for stable operation.

C_{OUT} can reduce ripple of Output Voltage, therefore $47\mu F$ or more value of tantalum type capacitor is recommended.

4. L_x Transistor

Pch Power MOSFET is required for this IC.

Its breakdown voltage between gate and source should be a few V higher than Input Voltage.

In the case of Input Voltage is low, to turn on MOSFET completely, to use a MOSFET with low threshold voltage is effective.

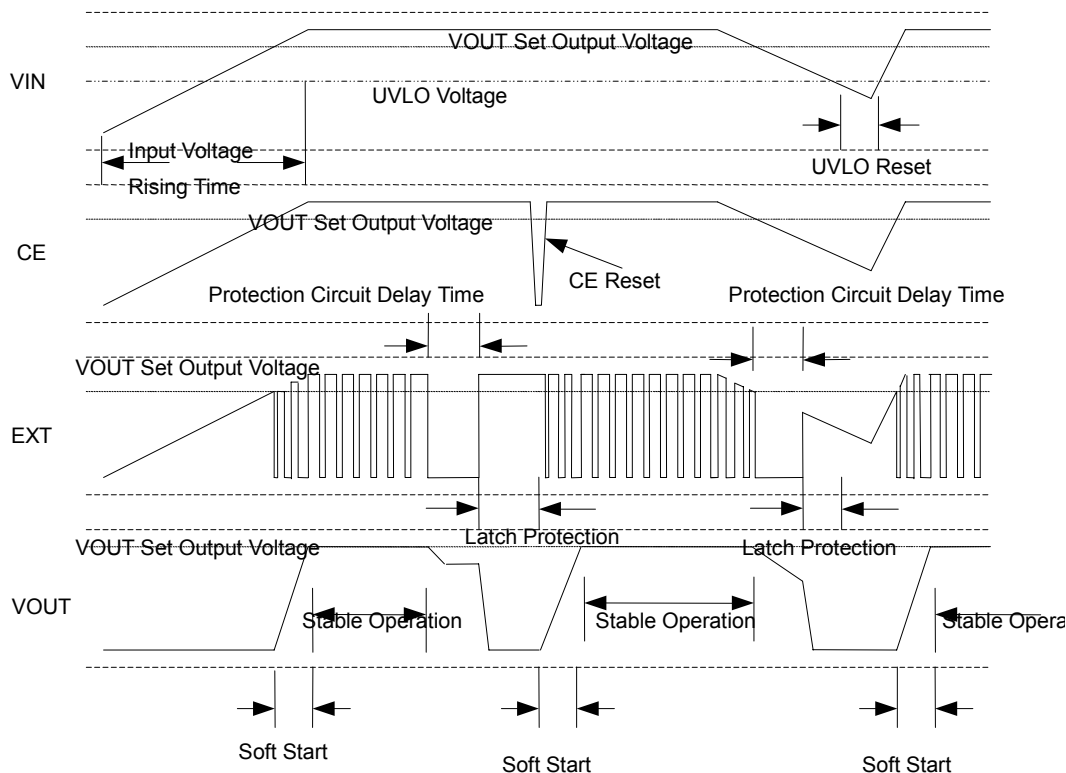

If a large load current is necessary for your application and important, choose a MOSFET with low ON resistance for good efficiency.

If a small load current is mainly necessary for your application, choose a MOSFET with low gate capacity for good efficiency.

Maximum continuous drain current of MOSFET should be larger than peak current, I_{Lmax} .

TIMING CHART

Case 1. Set VOUT Voltage >2.1V (Set VOUT Voltage>UVLO Voltage)

The timing chart shown above describes the changing process of input voltage rising, stable operating, operating with large current, reset with CE pin, stable operating, input voltage falling, input voltage recovering, and stable operating.

First, until when the input voltage (VIN) reaches the set output voltage, the circuit inside keeps the condition of pre-standby.

Second, after VIN becomes beyond the set output voltage, soft-start operation starts, when the soft-start operation finishes, the operation becomes stable.

If too large current flows through the circuit because of short or other reasons, EXT signal ignores that during the delay time of protection circuit. (The current value depends on the circuit.)

After the delay time passes, the latch protection works, or EXT signal will be "H", then output will turn off. To release the latch protection, input voltage should be equal or lower than UVLO level, or restart with CE (Once turn off the circuit with CE and turn it on again). In the timing charge above, release the latch function is realized with CE signal from "L" to "H". After removing the cause of large current and the reset with CE, soft-start operation starts and after the soft-start time, the operation will be back to stable.

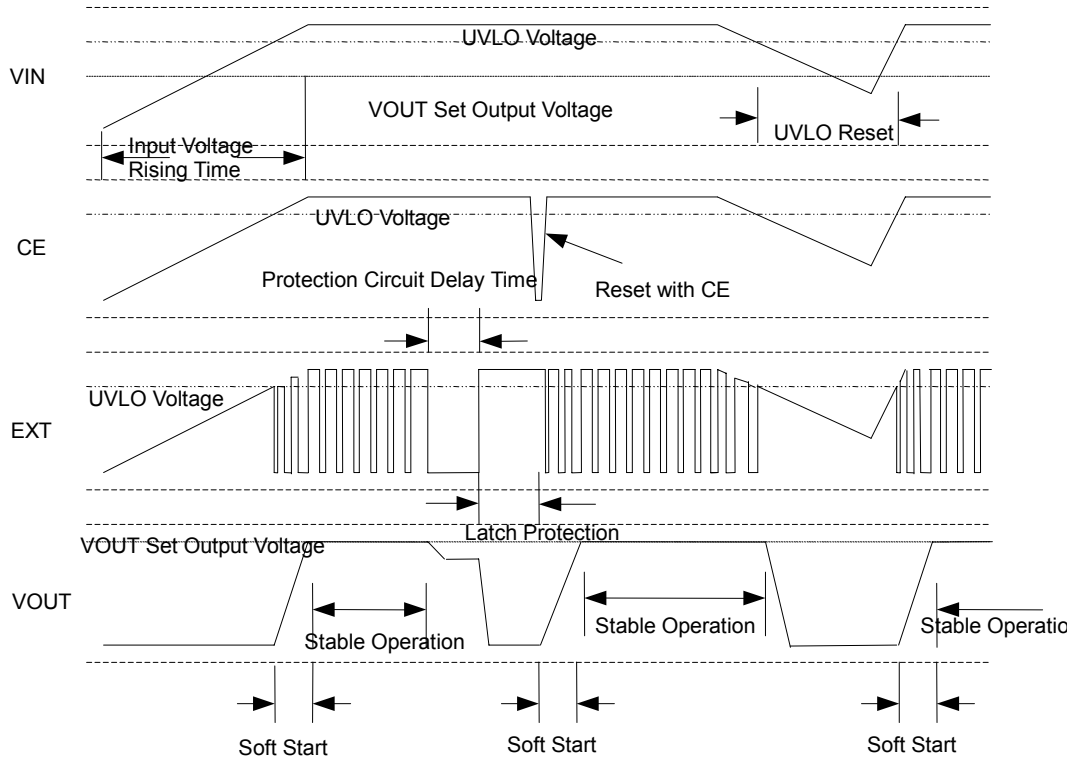

If the VIN becomes lower than the set VOUT, that situation is same as large current condition, so protection circuit may be ready to work, therefore, after the delay time of protection circuit, EXT will be "H" and the output turns off.

Further, if the VIN is lower than UVLO voltage, the circuit inside will be stopped by UVLO function.

After that, if VIN rises, until when the VIN reaches the set output voltage, the circuit inside keeps the condition of pre-standby.

Then after VIN becomes beyond the set output voltage, soft-start operation starts, when the soft-start operation finishes, the operation becomes stable.

Case 2. Set VOUT Voltage \leq 2.0V (Set VOUT Voltage < UVLO Voltage)

The timing chart shown above describes the changing process of input voltage rising, stable operating, operating with large current, reset with CE pin, stable operating, input voltage falling, input voltage recovering, and stable operating.

First, until when the input voltage (VIN) reaches the UVLO voltage, the circuit inside keeps the condition of pre-standby.

Second, after VIN becomes beyond the UVLO voltage, soft-start operation starts, when the soft-start operation finishes, the operation becomes stable.

If too large current flows through the circuit because of short or other reasons, EXT signal ignores that during the delay time of protection circuit. (The current value depends on the circuit.)

After the delay time passes, the latch protection works, or EXT signal will be "H", then output will turn off. To release the latch protection, input voltage should be equal or lower than UVLO level, or restart with CE (Once turn off the circuit with CE and turn it on again). In the timing charge above, release the latch function is realized with CE signal from "L" to "H". After removing the cause of large current and the reset with CE, soft-start operation starts and after the soft-start time, the operation will be back to stable.

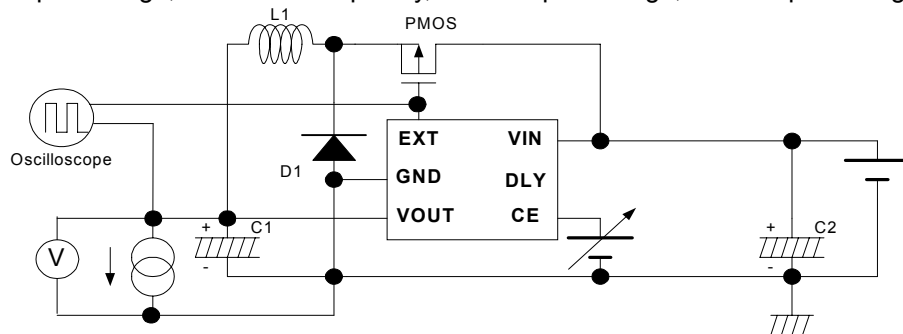

Further, if the VIN is lower than UVLO voltage, the circuit inside will be stopped by UVLO function.

After that, if VIN rises, until when the VIN reaches UVLO voltage, the circuit inside keeps the condition of pre-standby.

Then after VIN becomes beyond the UVLO voltage, soft-start operation starts, when the soft-start operation finishes, the operation becomes stable.
