Note)

\*1. Differential gain and differential phase conditions.

\*2. Aliasing noise

Measure with a spectrum analyzer the 4.43 MHz output signal voltage at 3.58 MHz input (clock frequency 16.02 MHz).

\*3. Insertion gain difference

With the insertion gain of clock frequencies of 15.2 MHz, 21.4 MHz and 27.2 MHz, determine maximum value as IGmax [dB] and minimum value as IGmin [dB]. Insertion gain difference ΔIG is defined as follows.

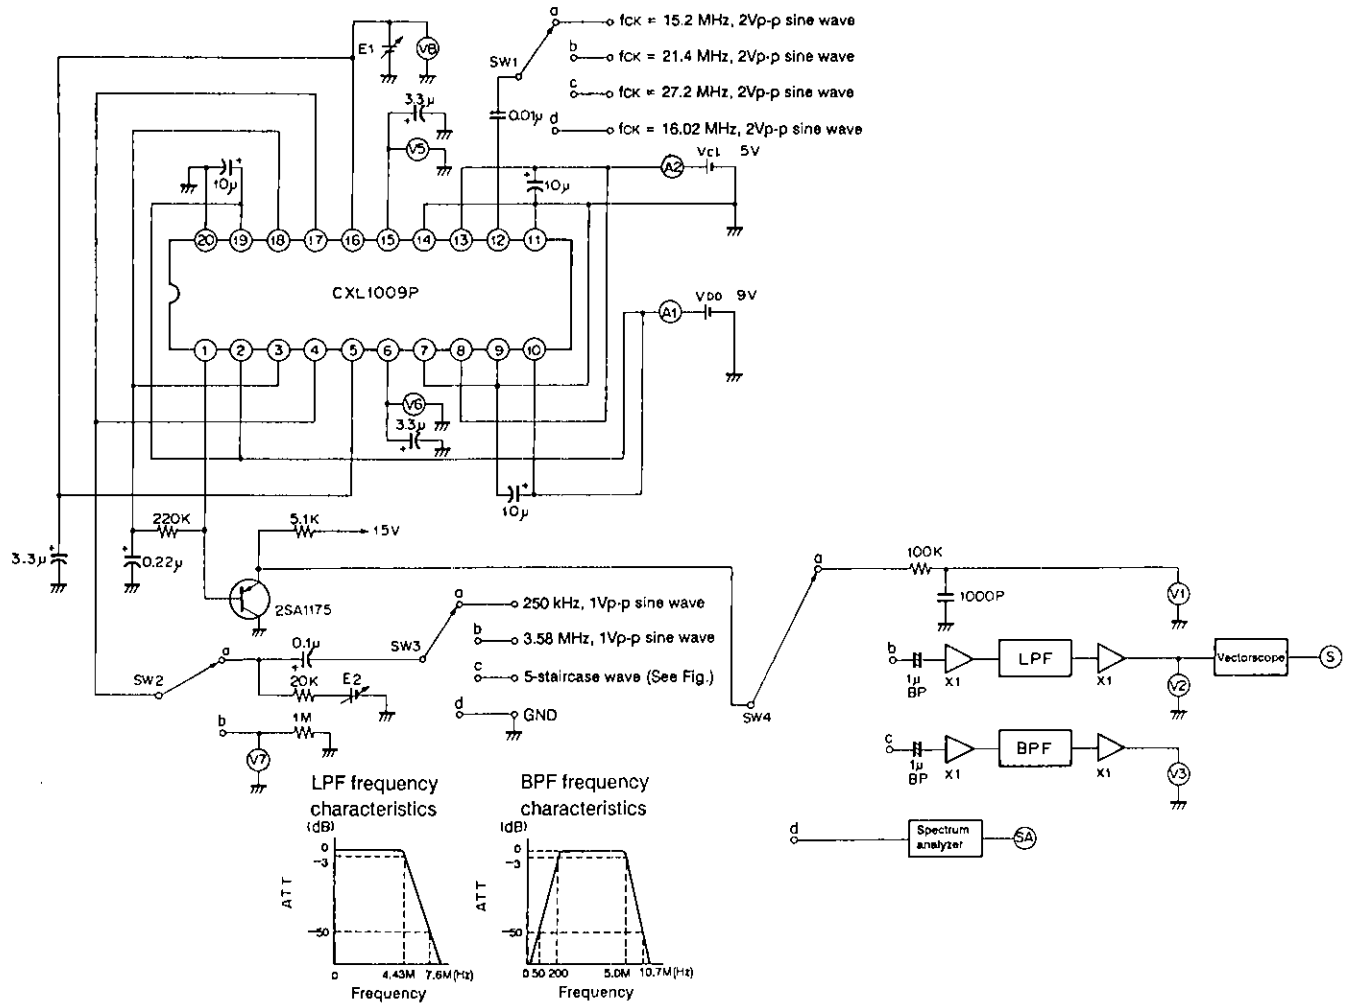

$$\Delta IG = \frac{10^{(IG_{max}/20)} - 10^{(IG_{min}/20)}}{10^{(IG_{max}/20)} + 10^{(IG_{min}/20)}} \times 200 [\%]$$

\*4. DC output voltage difference

With the DC output voltage of clock frequencies of 15.2 MHz, 21.4MHz and 27.2 MHz, determine maximum value as VO-DCmax and minimum value as VO-DCmin. DC output voltage difference ΔVO-DC is defined as follows.

$$\Delta VO-DC = VO-DC_{max} - VO-DC_{min} [V]$$
